COMPOUNDS

The present invention relates to pyrrolobenzodiazepines (PBDs).

Background to the invention

5 Some pyrrolobenzodiazepines (PBDs) have the ability to recognise and bond to specific sequences of DNA; the preferred sequence is PuGpu. The first PBD antitumour antibiotic, anthramycin, was discovered in 1965 (Leimgruber et al., 1965 *J. Am. Chem. Soc.*, **87**, 5793-5795; Leimgruber et al., 1965 *J.*
10 *Am. Chem. Soc.*, **87**, 5791-5793). Since then, a number of naturally occurring PBDs have been reported, and over 10 synthetic routes have been developed to a variety of analogues (Thurston et al., 1994 *Chem. Rev.* **1994**, 433-465). Family members include abbeymycin (Hochlowski et al., 1987 *J.*
15 *Antibiotics*, **40**, 145-148), chicamycin (Konishi et al., 1984 *J. Antibiotics*, **37**, 200-206), DC-81 (Japanese Patent 58-180 487; Thurston et al., 1990, *Chem. Brit.*, **26**, 767-772; Bose et al., 1992 *Tetrahedron*, **48**, 751-758), mazethramycin (Kuminoto et al., 1980 *J. Antibiotics*, **33**, 665-667), neothramycins A and B
20 (Takeuchi et al., 1976 *J. Antibiotics*, **29**, 93-96), porothramycin (Tsunakawa et al., 1988 *J. Antibiotics*, **41**, 1366-1373), prothracarcin (Shimizu et al, 1982 *J. Antibiotics*, **29**, 2492-2503; Langley and Thurston, 1987 *J. Org. Chem.*, **52**, 91-97), sibanomicin (DC-102) (Hara et al., 1988 *J. Antibiotics*,
25 **41**, 702-704; Itoh et al., 1988 *J. Antibiotics*, **41**, 1281-1284), sibiromycin (Leber et al., 1988 *J. Am. Chem. Soc.*, **110**, 2992-2993) and tomamycin (Arima et al., 1972 *J. Antibiotics*, **25**, 437-444). PBDs are of the general structure:

30 They differ in the number, type and position of substituents, in both their aromatic A rings and pyrrolo C rings, and in the degree of saturation of the C ring. In the B-ring there is

either an imine (N=C), a carbinolamine (NH-CH(OH)), or a carbinolamine methyl ether (NH-CH(OMe)) at the N10-C11 position which is the electrophilic centre responsible for alkylating DNA. All of the known natural products have an (S)-configuration at the chiral C11a position which provides them with a right-handed twist when viewed from the C ring towards the A ring. This gives them the appropriate three-dimensional shape for isohelicity with the minor groove of B-form DNA, leading to a snug fit at the binding site (Kohn, 1975 In *Antibiotics III*. Springer-Verlag, New York, pp. 3-11 ; Hurley and Needham-VanDevanter, 1986 *Acc. Chem. Res.*, **19**, 230-237). Their ability to form an adduct in the minor groove, enables them to interfere with DNA processing, hence their use as antitumour agents.

Disclosure of the invention

A first aspect of the present invention is a compound with the formula **Ia** or **Ib**:

(Ia)

(Ib)

wherein:

A is CH₂, or a single bond;

R₂ is selected from: R, OH, OR, CO₂H, CO₂R, COH, COR, SO₂R, CN; R₆, R₇ and R₈ are independently selected from H, R, OH, OR, halo, amino, NHR, nitro, Me₃Sn;

where R is a lower alkyl group having 1 to 10 carbon atoms, or an aralkyl group (i.e. an alkyl group with one or more aryl substituents), preferably of up to 12 carbon atoms, whereof the alkyl group optionally contains one or more carbon-carbon double or triple bonds, which may form part of a conjugated system, or an aryl group, preferably of up to 12 carbon atoms; and is optionally substituted by one or more halo, hydroxy,

amino, or nitro groups, and optionally containing one or more hetero atoms which may form part of, or be, a functional group; or R_7 and R_8 together form a group $-O-(CH_2)_p-O-$, where p is 1 or 2;

5 and R_8 is selected from H, R, OH, OR, halo, amino, NHR, nitro, Me_3Sn , where R is as defined above, or the compound is a dimer with each monomer being the same or different and being of formula **Ia** or **Ib**, where the R_8 groups of the monomers form together a bridge having the formula $-X-R'-X-$ linking the
10 monomers, where R' is an alkylene chain containing from 3 to 12 carbon atoms, which chain may be interrupted by one or more hetero-atoms and/or aromatic rings, e.g. benzene or pyridine, and may contain one or more carbon-carbon double or triple bonds, and each X is independently selected from O, S, or N;
15 except that in a compound of formula **Ia** when A is a single bond, then R_2 is not $CH=CH(CONH_2)$ or $CH=CH(CONMe_2)$.

If A is a single bond then R_2 is bonded directly to the C-ring of the PBD.

20 If R is an aryl group, and contains a hetero atom, then R is a heterocyclic group. If R is an alkyl chain, and contains a hetero atom, the hetero atom may be located anywhere in the alkyl chain, e.g. $-O-C_2H_5$, $-CH_2-S-CH_3$, or may form part of or be a functional group e.g. carbonyl, hydroxy.

25 It is preferred that in a compound of formula **Ia** when A is a single bond, then R_2 is not $CH=CR^A R^B$, where R^A and R^B are independently selected from H, R^C , COR^C , $CONH_2$, $CONHR^C$, $CONR^C$, cyano or phosphonate, where R^C is an unsubstituted alkyl group having 1 to 4 carbon atoms.

30 R is preferably selected from a lower alkyl group having 1 to 10 carbon atoms, or an aralkyl group, preferably of up to 12 carbon atoms, or an aryl group, preferably of up to 12 carbon atoms, optionally substituted by one or more halo, hydroxy, amino, or nitro groups. It is more preferred that R is selected from a lower alkyl group having 1 to 10 carbon atoms
35 optionally substituted by one or more halo, hydroxy, amino, or

nitro groups. It is particularly preferred that R is an unsubstituted straight or branched chain alkyl, having 1 to 10, preferably 1 to 6, and more preferably 1 to 4, carbon atoms, e.g. methyl, ethyl, n-propyl, n-butyl or t-butyl.

- 5 Alternatively, R_6 , R_7 , R_8 and, unless the compound is a dimer, R_9 may preferably be independently selected from R groups with the following structural characteristics:
- (i) an optionally substituted phenyl group;
 - (ii) an optionally substituted ethenyl group;
 - 10 (iii) an ethenyl group conjugated to an electron sink.

The term 'electron sink' means a moiety covalently attached to a compound which is capable of reducing electron density in other parts of the compound. Examples of electron sinks include cyano, carbonyl and ester groups.

- 15 It may be preferred that A is CH_2 and/or that R_2 is CO_2H , CO_2R , CH_2OH , or CH_2OR . It may be further preferred that R_2 is CO_2Me , CO_2^tBu , CH_2OH , or CH_2OAc .

- R_6 , R_7 , and R_9 , unless the compound is a dimer, R_8 are preferably selected from H and OR, and more particularly H, OMe and OCH_2Ph . It is further preferred that R_7 and, unless the compound is a dimer, R_8 are OR, more preferably OMe or OCH_2Ph , and that R_6 and R_9 are H.
- 20

- If A is a single bond, then R_2 is preferably an aryl group, eg Ph, p-MeO-Ph, or an alkyl or alkaryl group which contains at least one double bond which forms part of a conjugated system with the double bond of the C-ring, eg $\text{CH}=\text{CH}_2$, $\text{CH}=\text{CH}-\text{CH}_3$.
- 25

Compounds of the first aspect of the invention are preferably of formula **Ia**.

- If the compound of formula **Ia** or **Ib** is a dimer, the dimer bridge may be of the formula $-\text{O}-(\text{CH}_2)_p-\text{O}-$, where p is from 1 to 12, more preferably 3 to 9.
- 30

A second aspect of the present invention is a compound with the formula **II**:

wherein:

R'_2 is selected from: O, CHR''_2 , where R''_2 is selected from H, R, CO_2R , COR, CHO, CO_2H , halo;

R_6 , R_7 and R_8 are independently selected from H, R, OH, OR, halo, amino, NHR, nitro, Me_3Sn ;

where R is a lower alkyl group having 1 to 10 carbon atoms, or an aralkyl group (i.e. an alkyl group with one or more aryl substituents), preferably of up to 12 carbon atoms, whereof the alkyl group optionally contains one or more carbon-carbon double or triple bonds, which may form part of a conjugated system, or an aryl group, preferably of up to 12 carbon atoms; and is optionally substituted by one or more halo, hydroxy, amino, or nitro groups, and optionally containing one or more hetero atoms which may form part of, or be, a functional group;

and R_8 is selected from H, R, OH, OR, halo, amino, NHR, nitro, Me_3Sn , where R is as defined above or the compound is a dimer with each monomer being the same or different and being of formula **II**, where the R_8 groups of the monomers form together a bridge having the formula $-\text{X}-\text{R}'-\text{X}-$ linking the monomers, where R' is an alkylene chain containing from 3 to 12 carbon atoms, which chain may be interrupted by one or more hetero-atoms and/or aromatic rings, e.g. benzene or pyridine, and may contain one or more carbon-carbon double or triple bonds, and each X is independently selected from O, S, or N; or R_7 and R_8 together form a group $-\text{O}-(\text{CH}_2)_p-\text{O}-$, where p is 1 or 2; except that:

- (i) when R'_2 is CH-Et, and R_6 , R_8 and R_9 are H, R_7 is not sibirosamine pyranoside; and
- (ii) when R'_2 is CH-Me, and R_6 and R_9 are H, R_7 and R_8 are not both H or both OMe, or OMe and OH respectively.

If R is an aryl group, and contains a hetero atom, then R is a heterocyclic group. If R is an alkyl chain, and contains a hetero atom, the hetero atom may be located anywhere in the alkyl chain, e.g. $-O-C_2H_5$, $-CH_2-S-CH_3$, or may form part of or be a functional group e.g. carbonyl, hydroxy.

R is preferably selected from a lower alkyl group having 1 to 10 carbon atoms, or an aralkyl group, preferably of up to 12 carbon atoms, or an aryl group, preferably of up to 12 carbon atoms, optionally substituted by one or more halo, hydroxy, amino, or nitro groups. It is more preferred that R is selected from a lower alkyl group having 1 to 10 carbon atoms optionally substituted by one or more halo, hydroxy, amino, or nitro groups. It is particularly preferred that R is an unsubstituted straight or branched chain alkyl, having 1 to 10, preferably 1 to 6, and more preferably 1 to 4, carbon atoms, e.g. methyl, ethyl, n-propyl, n-butyl or t-butyl.

Alternatively, R_6 , R_7 , and R_8 , and, unless the compound is a dimer, R_9 may preferably be independently selected from R groups with the following structural characteristics:

- (i) an optionally substituted phenyl group;
- (ii) an optionally substituted ethenyl group;
- (iii) an ethenyl group conjugated to an electron sink.

R'_1 is preferably O, CH_2 , or $CHCH_3$, and more preferably CH_2 , or $CHCH_3$.

R_6 , R_7 , and R_8 , and, unless the compound is a dimer, R_9 are preferably selected from H and OR and a halogen atom, and more particularly H, OMe and OCH_2Ph , and I. It is further preferred that R_7 , and, unless the compound is a dimer, R_8 are OR or a halogen atom, more preferably OMe, OCH_2Ph or I, and that R_6 and R_9 are H. Most preferably R_9 is BnO.

If the compound of formula **II** is a dimer, the dimer bridge may be of the formula $-O-(CH_2)_p-O-$, where p is from 1 to 12, more preferably 3 to 9, and most preferably 3 to 5.

A third aspect of the present invention is a compound with the formula **III**:

wherein:

5 R_6 , R_7 , and R_9 are independently selected from H, R, OH, OR, halo, amino, NHR, nitro, Me_3Sn ;

where R is a lower alkyl group having 1 to 10 carbon atoms, or an aralkyl group (i.e. an alkyl group with one or more aryl substituents), preferably of up to 12 carbon atoms, whereof the alkyl group optionally contains one or more carbon-carbon double or triple bonds, which may form part of a conjugated system, or an aryl group, preferably of up to 12 carbon atoms; and is optionally substituted by one or more halo, hydroxy, amino, or nitro groups, and optionally containing one or more hetero atoms which may form part of, or be, a functional group; and R_8 is selected from H, R, OH, OR, halo, amino, NHR, nitro, Me_3Sn , where R is as defined above or the compound is a dimer with each monomer being the same or different and being of formula **III**, where the R_8 groups of the monomer form together a bridge having the formula $-X-R'-X-$ linking the monomers, where R' is an alkylene chain containing from 3 to 12 carbon atoms, which chain may be interrupted by one or more hetero-atoms and/or aromatic rings, e.g. benzene or pyridine, and may contain one or more carbon-carbon double or triple bonds, and each X is independently selected from O, S, or N; or R_7 and R_8 together form a group $-O-(CH_2)_p-O-$, where p is 1 or 2; wherein at least one of R_6 , R_7 , R_8 and R_9 are not H; except that:

- (i) when R_6 and R_9 are H, R_7 and R_8 are not both OMe, OMe and OBn respectively, or OMe and OH respectively;
- 30 (ii) when R_6 and R_7 are H, R_8 and R_9 are not Me and OH respectively;
- (iii) when three of R_6 , R_7 , R_8 and R_9 are H, the other is not Me;

- (iv) when R_6 , R_7 , and R_8 are H, R_9 is not OMe;
- (v) when R_6 , R_8 and R_9 are H, R_7 is not OMe; and
- (vi) when R_6 , and R_9 are H and R_7 is OMe, the compound is not a dimer.

5 If R is an aryl group, and contains a hetero atom, then R is a heterocyclic group. If R is an alkyl chain, and contains a hetero atom, the hetero atom may be located anywhere in the alkyl chain, e.g. $-O-C_2H_5$, $-CH_2-S-CH_3$, or may form part of or be a functional group e.g. carbonyl, hydroxy.

10 R is preferably selected from a lower alkyl group having 1 to 10 carbon atoms, or an aralkyl group, preferably of up to 12 carbon atoms, or an aryl group, preferably of up to 12 carbon atoms, optionally substituted by one or more halo, hydroxy, amino, or nitro groups. It is more preferred that R is
15 selected from a lower alkyl group having 1 to 10 carbon atoms optionally substituted by one or more halo, hydroxy, amino, or nitro groups. It is particularly preferred that R is an unsubstituted straight or branched chain alkyl, having 1 to 10, preferably 1 to 6, and more preferably 1 to 4, carbon
20 atoms, e.g. methyl, ethyl, n-propyl, n-butyl or t-butyl.

Alternatively, R_6 , R_7 and R_9 and, unless the compound is a dimer, R_8 , may preferably be independently selected from R groups with the following structural characteristics:

- (i) an optionally substituted phenyl group;
- 25 (ii) an optionally substituted ethenyl group;
- (iii) an ethenyl group conjugated to an electron sink.

It is preferred that either:

- (i) only one of R_6 , R_7 , R_8 and R_9 is H; or
- (ii) at least one of R_6 , R_7 , R_8 , and R_9 is NH_2 ; or
- 30 (iii) at least one of R_6 , R_7 , R_8 and R_9 is an aryl group, preferably of up to 12 carbon atoms, which is optionally substituted by one or more halo, hydroxy, amino, or nitro groups, and optionally contains one or more hetero atoms which may form part of, or be, a functional group.

If only one of R_6 , R_7 , R_8 and R_9 , it is further preferred that the A-ring substituents (i.e. those of R_6 , R_7 , R_8 and, unless the compound is a dimer, R_9 which are not H) are OR, and are more preferably selected from OMe, and OBn.

- 5 If at least one of R_6 , R_7 , R_8 and R_9 is an aryl group, preferably of up to 12 carbon atoms, which is optionally substituted by one or more halo, hydroxy, amino, or nitro groups, and optionally contains one or more hetero atoms which may form part of, or be, a functional group, it is further
- 10 preferred that at least one of R_6 , R_7 , R_8 and R_9 , is a phenyl group optionally substituted by one or more methoxy, ethoxy or nitro groups, although the nitro groups are less preferred. More preferably, the aryl group is selected from: Ph and p-MeO-Ph.
- 15 If the compound of formula **III** is a dimer, the dimer bridge may be of the formula $-O-(CH_2)_p-O-$, where p is from 1 to 12, more preferably 3 to 9. Also in this case, it is preferred that R_6 and R_9 are H, and R_7 is an alkoxy or aryloxy group.

20 A fourth aspect of the present invention provides a compound with the formula **IV**:

wherein:

R_6 , R_7 and R_9 are independently selected from H, R, OH, OR, halo, amino, NHR, nitro, Me_3Sn ;

25 where R is a lower alkyl group having 1 to 10 carbon atoms, or an aralkyl group (i.e. an alkyl group with one or more aryl substituents), preferably of up to 12 carbon atoms, whereof the alkyl group optionally contains one or more carbon-carbon double or triple bonds, which may form part of a conjugated system, or an aryl group, preferably of up to 12 carbon atoms;

and is optionally substituted by one or more halo, hydroxy, amino, or nitro groups, and optionally containing one or more hetero atoms which may form part of, or be, a functional group;

- 5 R_8' and R_8'' are either independently selected from H, R or together form a cyclic amine; and
n is from 1 to 7.

10 If R_8' and R_8'' form a cyclic amine, then there is usually a single N atom in a ring which is otherwise carbocyclic and is preferably 5- or 6- membered and may be saturated or unsaturated. The ring may be fused to another ring system which may be aromatic, e.g. being a benzene ring. Thus for example the cyclic amine may be an indolyl or isoindolyl group. It is also possible that the cyclic amine contains one
15 or more hetero atoms, in addition to N in the amine ring and/or in a fused ring and may also be substituted by one or more R groups.

If R is an aryl group, and contains a hetero atom, then R is a heterocyclic group. If R is an alkyl chain, and contains a
20 hetero atom, the hetero atom may be located anywhere in the alkyl chain, e.g. $-O-C_2H_5$, $-CH_2-S-CH_3$, or may form part of or be a functional group e.g. carbonyl, hydroxy.

R is preferably selected from a lower alkyl group having 1 to 10 carbon atoms, or an aralkyl group, preferably of up to 12
25 carbon atoms, or an aryl group, preferably of up to 12 carbon atoms, optionally substituted by one or more halo, hydroxy, amino, or nitro groups. It is more preferred that R is selected from a lower alkyl group having 1 to 10 carbon atoms optionally substituted by one or more halo, hydroxy, amino, or
30 nitro groups. It is particularly preferred that R is an unsubstituted straight or branched chain alkyl, having 1 to 10, preferably 1 to 6, and more preferably 1 to 4, carbon atoms, e.g. methyl, ethyl, n-propyl, n-butyl or t-butyl.

It may be preferred that one of R_8' and R_8'' is a nitrogen
35 protecting group, such as Fmoc.

R₇ is preferably an electron donating group, and is more preferably of the formula OR; particularly preferred are the groups OMe, OEt, and OBn. The term 'electron donating group' means a moiety covalently attached to a compound which is capable of increasing electron density in other parts of the compound.

In addition R₆ and R₈ are more preferably selected from H and OR; particularly preferred are OMe, OEt and OBn.

Alternatively, R₆, R₇ and R₈ may preferably be independently selected from R groups with the following structural characteristics:

- (i) an optionally substituted phenyl group;
- (ii) an optionally substituted ethenyl group;
- (iii) an ethenyl group conjugated to an electron sink.

n is preferably 1 to 3, and more preferably 1.

A fifth aspect of the present invention is the use of a compound as described in the first, second, third or fourth aspects of the invention in a method of therapy. Conditions which may be treated include gene-based diseases, including, for example, neoplastic diseases and Alzheimer's Disease, and also bacterial, parasitic and viral infections. Any condition which may be treated by the regulation of gene expression may be treated using compounds of the invention. In accordance with this aspect of the present invention, the compounds provided may be administered to individuals. Administration is preferably in a "therapeutically effective amount", this being sufficient to show benefit to a patient. Such benefit may be at least amelioration of at least one symptom. The actual amount administered, and rate and time-course of administration, will depend on the nature and severity of what is being treated. Prescription of treatment, e.g. decisions on dosage, is within the responsibility of general practitioners and other medical doctors.

A compound may be administered alone or in combination with

other treatments, either simultaneously or sequentially dependent upon the condition to be treated.

Pharmaceutical compositions according to the present invention, and for use in accordance with the present invention, may comprise, in addition to the active ingredient, i.e. a compound of formula **Ia**, **Ib**, **II**, **III** or **IV**, a pharmaceutically acceptable excipient, carrier, buffer, stabiliser or other materials well known to those skilled in the art. Such materials should be non-toxic and should not interfere with the efficacy of the active ingredient. The precise nature of the carrier or other material will depend on the route of administration, which may be oral, or by injection, e.g. cutaneous, subcutaneous, or intravenous.

Pharmaceutical compositions for oral administration may be in tablet, capsule, powder or liquid form. A tablet may comprise a solid carrier or an adjuvant. Liquid pharmaceutical compositions generally comprise a liquid carrier such as water, petroleum, animal or vegetable oils, mineral oil or synthetic oil. Physiological saline solution, dextrose or other saccharide solution or glycols such as ethylene glycol, propylene glycol or polyethylene glycol may be included. A capsule may comprise a solid carrier such as a gelatin.

For intravenous, cutaneous or subcutaneous injection, or injection at the site of affliction, the active ingredient will be in the form of a parenterally acceptable aqueous solution which is pyrogen-free and has suitable pH, isotonicity and stability. Those of relevant skill in the art are well able to prepare suitable solutions using, for example, isotonic vehicles such as Sodium Chloride Injection, Ringer's Injection, Lactated Ringer's Injection. Preservatives, stabilisers, buffers, antioxidants and/or other additives may be included, as required.

A sixth aspect of the present invention is a pharmaceutical composition containing a compound of any one of formulae **Ia**, **Ib**, **II**, **III**, or **IV** as described above, and a pharmaceutically

acceptable carrier or diluent. The preparation of pharmaceutical compositions is described in relation to the fifth aspect of the invention above.

5 A seventh aspect of the present invention provides the use of a compound of any one of formulae **Ia**, **Ib**, **II**, **III**, or **IV** as described above to prepare a medicament for the treatment of a gene-based disease, preferably a proliferative disease. The compound of formula **Ia**, **Ib**, **II**, **III**, or **IV** may be provided together with a pharmaceutically acceptable carrier or
10 diluent. The compounds may be used for the selective killing of oxic and hypoxic tumour cells in methods for the treatment of cancers, for example leukemias and particularly solid cancers including colon, CNS, renal, and lung tumours, including small cell lung carcinoma, and melanomas. In
15 particular, dimers of formula **II** may be used for the selective killing of lung, colon, and CNS tumours and melanomas. The compounds of formula **III** and **IV** may be used selectively against melanomas.

Preferred General Synthetic Strategies

A key step in a preferred route to compounds of formula **Ia**,
Ib, **II**, **III** or **IV** is a cyclisation to produce the B-ring,
 involving generation of an aldehyde (or functional equivalent
 thereof) at what will be the 11-position, and attack thereon
 by the Pro-N10-nitrogen:

In this structure, no C-ring substitution or unsaturation is
 shown. R_8 represents $O(CH_2)_nCH_2COR'_8$ in compounds of formula **IV**.
 R_{10} is a nitrogen protecting group, preferably with a carbamate
 functionality bonded to the nitrogen of the PBD. The "masked
 aldehyde" -CPQ may be an acetal or thioacetal (possibly
 cyclic), in which case the cyclisation involves unmasking.
 Alternatively, the masked aldehyde may be an aldehyde
 precursor, such as alcohol -CHOH, in which case the reaction
 involves oxidation, e.g. by means of TPAP or DMSO (Swern
 oxidation).

The masked aldehyde compound can be produced by condensing a
 corresponding 2-substituted pyrrolidine with a 2-nitrobenzoic
 acid:

The nitro group can then be reduced to -NH_2 and protected by reaction with a suitable reagent, e.g. a chloroformate, which provides the removable nitrogen protecting group in the synthesis route.

- 5 A process involving the oxidation-cyclization procedure is illustrated in scheme 1 (an alternative type of cyclisation will be described later with reference to scheme 2).

Scheme 1

- 10 The imine/carbinolamine bond in the PBD (**A**) can be unprotected by standard methods to yield the desired compound, e.g. if R_{10} is Alloc, then the deprotection is carried out using palladium to remove the N10 protecting group, followed by the elimination of water to give the imine.

- 15 Exposure of the alcohol (**B**) (in which the Pro-N10-nitrogen is generally protected as carbamate) to tetrapropylammonium

perruthenate (TPAP)/N-methylmorpholine N-oxide (NMO) over A4 sieves results in oxidation accompanied by spontaneous B-ring closure to afford the desired product. The TPAP/NMO oxidation procedure is found to be particularly convenient for small scale reactions while the use of DMSO-based oxidation methods, particularly Swern oxidation, proves superior for larger scale work (e.g. > 1 g).

The uncyclized alcohol (**B**) may be prepared by the reaction of a nitrogen protection reagent of formula **D**, which is preferably a chloroformate or acid chloride, to a solution of the amino alcohol **C**, generally in solution, generally in the presence of a base such as pyridine (preferably 2 equivalents) at a moderate temperature (e.g. at 0°C). Under these conditions little or no O-acylation is usually observed.

The key amino alcohol **C** may be prepared by reduction of the corresponding nitro compound **E**, by choosing a method which will leave the rest of the molecule intact. Treatment of **E** with tin (II) chloride in a suitable solvent, e.g. refluxing methanol, generally affords, after the removal of the tin salts, the desired product in high yield.

Exposure of **E** to hydrazine/Raney nickel avoids the production of tin salts and may result in a higher yield of **C**, although this method is less compatible with the range of possible **C** and A-ring substituents. For instance, if there is C-ring unsaturation (either in the ring itself, or in R₂ or R₃), this technique may be unsuitable.

The nitro compound of formula **E** may be prepared by coupling the appropriate o-nitrobenzoyl chloride to a compound of formula **F**, e.g. in the presence of K₂CO₃ at -25°C under a N₂ atmosphere. Compounds of formula **F** can be readily prepared, for example by olefination of the ketone derived from L-trans-hydroxy proline. The ketone intermediate can also be exploited by conversion to the enol triflate for use in palladium mediated coupling reactions.

The *o*-nitrobenzoyl chloride is synthesised from the *o*-nitrobenzoic acid (or alkyl ester after hydrolysis) of formula **G**, which itself is prepared from the vanillic acid (or alkyl ester) derivative **H**. Many of these are commercially available and some are disclosed in Althuis, T.H. and Hess, H.J., *J. Medicinal Chem.*, 20(1), 146-266 (1977).

Alternative Cyclisation (Scheme 2)

Scheme 2

In scheme 1, the final or penultimate step was an oxidative cyclisation. An alternative, using thioacetal coupling, is shown in scheme 2. Mercury-mediated unmasking causes cyclisation to the protected PBD compound (**A**).

The thioacetal compound may be prepared as shown in scheme 2: the thioacetal protected C-ring [prepared via a literature method: Langley, D.R. & Thurston, D.E., *J. Organic Chemistry*, **52**, 91-97 (1987)] is coupled to the *o*-nitrobenzoic acid (or alkyl ester after hydrolysis) (**G**) using a literature procedure. The resulting nitro compound cannot be reduced by hydrogenation, because of the thioacetal group, so the tin(II)

chloride method is used to afford the amine. This is then N-protected, e.g., by reaction with a chloroformate or acid chloride, such as 2,2,2-trichloroethylchloroformate.

5 Acetal-containing C-rings can be used as an alternative in this type of route with deprotection involving other methods, including the use of acidic conditions.

Dimer Synthesis (Scheme 3)

Scheme 3

10 PBD dimers may be synthesized using the strategy developed for the synthesis of the protected PBD monomers. The synthesis routes illustrated in scheme 3 show compounds when the dimer linkage is of the formula $-O-(CH_2)_n-O-$. The step of dimer formation is normally carried out to form a bis(nitro acid) **G'**. This compound can then be treated as compound **G** in
15 either scheme 1 or scheme 2 above.

The bis(nitro acid) **G'** may be obtained by nitrating (e.g. using 70% nitric acid) the bis(carboxylic acid). This can be

synthesised by alkylation of two equivalents of the relevant benzoic acid with the appropriate diiodoalkane under basic conditions. Many benzoic acids are commercially available and others can be synthesised by conventional methods.

5 Alternatively, the relevant benzoic acid esters can be joined together by a Mitsunobo etherification with an appropriate alkanediol, followed by nitration, and then hydrolysis (not illustrated).

10 An alternative synthesis of the bis(nitro acid) involves oxidation of the bis(nitro aldehyde), e.g. with potassium permanganate. This can be obtained in turn by direct nitration of the bis(aldehyde), e.g. with 70% HNO₃. Finally, the bis(aldehyde) can be obtained via the Mitsunobu etherification of two equivalents of the benzoic aldehyde with
15 the appropriate alkanediol.

An alternative synthesis approach to those detailed above is to protect the pro N10 position on the component which will form the A-ring, before joining the component which will form the C-ring.

20 **Preferred Synthetic Strategies for Compounds of formula Ia**

The synthesis route of scheme 1 is generally applicable to compounds of formula Ia.

25 C2/C3-endo-unsaturated PBDs of formula Ia may be synthesised from their N10-carbamate protected precursors. Typically, palladium catalysed removal of an allyl carbamate may be used to generate the N10-C11 imine without affecting the key C2-unsaturation. For example, if the N10-C11 imine/carbinolamine is protected by an Alloc group, the C2/C3-endo-unsaturation is maintained during the Alloc cleavage reaction.

30 The reduction of the nitro-compound **E** as shown in scheme 1 with tin (II) chloride in refluxing methanol leaves the C2/C3-unsaturation unaffected. The hydrazine/Raney nickel method would not be suitable due to the double bond.

The compound of formula **F** may be used in its TBDMS protected form, and therefore a deprotection step has to be included to produce the amino-alcohol compound **E**.

5 The TBDMS ether, which is the product of the coupling of TBDMS protected compound with the appropriate *o*-nitrobenzoyl chloride, can be treated with AcOH:THF:H₂O (3:1:1). TBAF was found to be unsuitable for this transformation due to the rapid degradation of reaction products.

10 A class of requisite C-ring providing compounds **F** can be obtained as shown in scheme 4.

Scheme 4

15 Commercially available *trans*-4-hydroxy-L-proline **F8** can be N-alloc protected to give the allyl carbamate **F7** which can then be esterified using standard conditions. Hydride reduction of the ester **F6** furnishes the diol **F5**. Selective TBDMS protection of the diol gives a silyl ether **F4**, which can then be oxidised, using either Swern or TPAP oxidation, to provide the ketone **F3**.

20 The ketone **F3** can then undergo a Wittig reaction to yield a mixture of the *E/Z* *exo*-esters **F2** which can then be converted to the C2/C3-*endo* compound **F1(1a)** upon treatment with excess sodium

hydride. Palladium-mediated cleavage of the N-alloc protecting group (Dangles O.; Guibé, F.; Balavoine, G.; Lavielle, S.; Marquet, A.; *J. Org. Chem.* **1987**, 52, 4984) yields the compound **F(Ia)**.

5 Alternative route to compounds of formula Ia

A more linear synthetic route to compound **B** of scheme 1 has been developed which enables larger scale production of the C2/C3-endo-unsaturated PBDs, and is shown in scheme 5.

Scheme 5

10 The silyl protecting group may be cleaved in good yield by treating **B1(Ia)** with AcOH:THF:H₂O (3:1:1). The key C2/C3-endo-

unsaturation present in **B1(Ia)** may be introduced directly by performing the Horner-Emmons reaction on a ketone of type **B2**. Unlike the previous route (**Scheme 4**), the addition of extra NaH to ensure double-bond migration was not necessary for this substrate. Swern oxidation of the secondary alcohol **B3** may be used to furnish the ketone **B2**. The carbamate protected aniline **B3** may be prepared from the nitro compound **B5** in two steps. Firstly, the nitro group may be reduced to the aniline by employing the Raney nickel/hydrazine method because a compound of type **B5** lacks C2-unsaturation. This method is more advantageous than the tin (II) chloride procedure since the product is easier to isolate. The aniline **B4** may then be N-carbamate protected in high yield without significant carbonate formation at the C2 oxygen.

An amide of type **B5** may be synthesised by coupling an acid chloride of type **G** to the key amine **KEC5** (**Scheme 6**).

Scheme 6

Overall, this route has several advantages over the previous route which results in the larger scale production of the C2/C3-endo-unsaturated PBDs. Firstly, catalytic hydrogenation of **KEC4** allows large scale preparation of key intermediate **KEC5**. Secondly, this more efficient nitro reduction step may be carried out on an intermediate devoid of C2-unsaturation. Importantly, the double-bond migration observed during the

Horner-Emmons reaction is spontaneous, so excess sodium hydride is not necessary. This double-bond migration has also been observed by other workers (Leimgruber, W.; Batcho, A. D.; Czajkowski, R. C. *J. Am. Chem. Soc.* **1968**, *90*, 5641).

5 Parr-hydrogenation of **KEC4**, in order to cleave the Cbz protecting group, allowed the large scale synthesis of the key amino intermediate **KEC5**. The TBDMS ether **KEC4** was prepared in an analogous fashion to the corresponding Alloc protected intermediate **F4** (Scheme 4). Selective silylation of the
10 primary alcohol **KEC3** was achieved using DBU as a silyl transfer agent. The diol **KEC3** was obtained from hydride reduction of ester **KEC2** which in turn was synthesised from carboxylic acid **KEC1**. N-Cbz protection of *trans*-4-hydroxy-L-proline (**F4**) was achieved by adopting a procedure reported in
15 the literature (Bridges, R. J.; Stanley, M. S.; Anderson, M. W.; Cotman, C. W.; Chamberlain, R. A. *J. Med. Chem.* **1991**, *34*, 717).

Certain R₂ groups may require protection during the synthesis routes set out above, e.g. alcohols can be protected by using
20 an acetate protecting group (see example 1(d))

Further alternative route to compound of formula Ia

Scheme 7

The following route is particularly suited to a compound of formula **Ia** where A is a single bond, and R_2 is an allyl group or contains a double bond which is conjugated to that in the C-ring. However, elements of the synthesis, eg the SEM protection, may be useful in a route to other compounds.

The target PBDs were prepared by reduction of the SEM

protected dilactam (Q) with sodium tetraborohydride followed by treatment with silica gel. The sodium tetraborohydride, initially, converts the dilactam into a protected carbinolamine. However, this species is very unstable and treatment with silica gel is sufficient to provoke fragmentation of the SEM protecting group accompanied by imine formation.

The SEM protected dilactams (Q) were prepared by Suzuki and Stille coupling reactions on the enol triflate intermediate (P). The Suzuki reaction is particularly useful as it can be used to install both aryl and vinyl substituents at the C2 position of the PBD. In excess of 70 boronic acids are commercially available allowing great diversity to be introduced into the PBD system. Heck reactions can also be performed smoothly on the enol triflate intermediate.

The enol triflate (P) was prepared from the ketone precursor (O) using triflic anhydride in DCM in the presence of pyridine. The ketone (O) was prepared from the secondary alcohol precursor (N) by Swern oxidation. Other oxidation methods involving TPAP or the Dess Martin reagent provide the ketone in equally good yields. The secondary alcohol was obtained by selective removal of a TBDMS group of compound M in the presence of the SEM N10 protecting group. The SEM group was installed by quenching the N10 dilactam anion (from L) with SEM-C1; this is a general method and can be used to install related protecting groups such as MOM. In order to prevent the C2 hydroxy of compound K interfering with the N10 protection step it was protected as a TBDMS ether. The 2-hydroxy dilactam (K) was formed by hydrogenating the A-ring nitro group of compound J and coupling to the C-ring methyl ester. The A-ring nitro C-ring ester compound (J) was prepared by coupling commercially available acid (G) to methyl 4-hydroxyprolinate.

The alternative synthesis routes are equally applicable to the synthesis of dimers.

Preferred Synthesis Strategies for Compounds of formula II

The synthesis route of scheme 1 is generally applicable to compounds of formula II.

5 C2-unsaturated PBDs of formula II may be synthesised from their N10-carbamate protected precursors. Typically, palladium catalysed removal of an allyl carbamate may be used to generate the N10-C11 imine without affecting the key C2-unsaturation. Alternatively, cadmium-lead couple may be employed to cleave an N10-2,2,2-trichloroethyl carbamate from
10 the protected PBD.

The reduction of the nitro-compound E as shown in scheme 1 with tin (II) chloride maintains the C2-unsaturation, although isolating the aniline C from the tin salts can be problematic.

15 The compound of formula F may be used in its TBDMS protected form, and therefore a deprotection step has to be included to produce the amino-alcohol compound E.

20 The TBDMS ether of type E, which is the product of the coupling of the TBDMS protected compound with the appropriate o-nitrobenzoyl chloride, can be treated with AcOH:THF:H₂O (3:1:1). TBAF was found to be unsuitable for this transformation due to the rapid degradation of reaction products.

C-ring providing compounds F(II) can be obtained as shown in scheme 8.

Scheme 8

Commercially available *trans*-4-hydroxy-L-proline **F8** can be N-alloc protected to give the allyl carbamate **F7** which can then be esterified using standard conditions. Hydride reduction of the ester **F6** furnishes the diol **F5**. Selective TBDMS protection of the diol gives a silyl ether **F4**, which can then be oxidised, using either Swern or TPAP oxidation, to provide the ketone **F3**.

The C2-olefinic functionality present in **F2** may be introduced by performing the Wittig reaction on ketone **F3**. Palladium-mediated cleavage of the N-alloc protecting group (Dangles O.; Guibé, F.; Balavoine, G.; Lavielle, S.; Marquet, A.; *J. Org. Chem.* **1987**, 52, 4984) yields compound **F(II)**.

Alternative route to compound C

Scheme 9

An alternative route to compound C has been developed (**Scheme 9**). The amide of formula **C1** may be synthesised by forming the acid chloride of an N-Troc protected anthranilic acid of type **C2**. Interestingly, N-Troc anthranilic acids do not generate isatoic anhydrides, thus enabling amide formation reactions with amines of type **F(II)**. Simultaneous TBAF-mediated cleavage of the 2,2,2- trichloroethyl carbamate and TBDMS groups from **C1** may provide the key amino-alcohol **C**.

Alternative Route to compounds of formula II

Scheme 10

A more linear synthetic route to compound **B** of scheme 1 has been developed which enables larger scale production of the C2-unsaturated PBDs, and is shown in scheme 10. TBAF-mediated cleavage of the TBDMS group may be used to produce **B(II)** from **B1(II)**. The key C2-unsaturation present in **B1(II)** may be introduced by performing the Wittig olefination reaction on a

ketone of type **B2**. Swern oxidation of the secondary alcohol **B3** may be used to furnish the ketone **B2**. The carbamate protected aniline **B3** may be prepared from the nitro compound **B5** in two steps. Firstly, the nitro group may be reduced to the aniline by employing the Raney nickel/hydrazine method because a compound of type **B5** lacks C2-unsaturation. This method is more advantageous than the tin (II) chloride procedure since the product is easier to isolate. The aniline **B4** may then be N-carbamate protected in high yield without significant carbonate formation at the C2 oxygen.

An amide of type **B5** may be synthesised by coupling an acid chloride of type **G** to the key amine **KEC5** (see scheme 6). Overall, this route has several advantages over the convergent route which allow larger scale production of the C2-unsaturated PBDs. Firstly, catalytic hydrogenation of **KEC4** allows large scale preparation of key intermediate **KEC5**. Secondly, the nitro reduction step may be carried out on an intermediate devoid of C2-unsaturation. Finally, the Wittig olefination may be performed in the latter stages of the synthetic route where large scale limitations are tolerated.

In dimer synthesis, the routes set out above may be used in preference to those set out in the overall synthetic strategies. In particular, the nitrogen-protecting group may advantageously be a carbamate, as protecting groups of this type may be removed in the final step by a variety of methods which, in general, do not affect the key C2-unsaturation.

General Experimental Methods

Melting points (mp) were determined on a Gallenkamp P1384 digital melting point apparatus and are uncorrected. Infrared (IR) spectra were recorded using a Perkin-Elmer 297 spectrophotometer. ¹H- and ¹³C- NMR spectra were recorded on a Jeol GSX 270 MHz FT-NMR spectrometer operating at 20°C +/-1°C. Chemical shifts are reported in parts per million (δ) downfield from tetramethylsilane (TMS). Spin multiplicities are described as: s (singlet), bs (broad singlet), d (doublet), dd (doublet of doublets), t (triplet), q (quartet),

p (pentuplet) or m (multiplet). Mass spectra (MS) were recorded using a Jeol JMS-DX 303 GC Mass Spectrometer (EI mode: 70eV, source 117-147°C). Accurate molecular masses (HRMS) were determined by peak matching using

5 perfluorokerosene (PFK) as an internal mass marker, and FAB mass spectra were obtained from a glycerol/thioglycerol/trifluoroacetic acid (1:1:0.1) matrix with a source temperature of 180°C. Optical rotations at the Na-D line were obtained at ambient temperature using a Perkin-

10 Elmer 141 Polarimeter. Analytical results were generally within +/-0.2% of the theoretical values. Flash chromatography was performed using Aldrich flash chromatography "Silica Gel-60" (E. Merck, 230-400 mesh). Thin-layer chromatography (TLC) was performed using GF₂₅₄ silica

15 gel (with fluorescent indicator) on glass plates. All solvents and reagents, unless otherwise stated, were supplied by the Aldrich Chemical Company Ltd. and were used as supplied without further purification. Anhydrous solvents were prepared by distillation under a dry nitrogen atmosphere in

20 the presence of an appropriate drying agent, and were stored over 4Å molecular sieves or sodium wire. Petroleum ether refers to the fraction boiling at 40-60°C.

Synthesis of the Alloc Pro-N10-Protected C2-Alcohol (5)

A solution of allyl chloroformate (1.54 mL, 14.48 mmol, 1.05 equiv) in freshly distilled CH₂Cl₂ (30 mL) was added dropwise to a stirred mixture of the amine **4** (6.70 g, 13.79 mmol, 1 equiv), pyridine (2.45 mL, 30.34 mmol, 2.2 equiv) in freshly distilled CH₂Cl₂ (200 mL), at 0°C under a nitrogen atmosphere. The mixture was allowed to warm at RT and stirred overnight. The following day TLC (SiO₂, 5% MeOH-CHCl₃) revealed reaction completion. The mixture was washed with saturated CuSO₄ (100 mL), H₂O (100 mL), brine (100 mL), dried (MgSO₄), filtered and evaporated *in vacuo* to give a dark yellow oil. A solution of the ester **13** (19.5 g, 85 mmol) in THF (326 mL) was cooled to 0°C (ice/acetone) and treated with LiBH₄ (2.78 g, 128 mmol) in portions. The reaction mixture was allowed to warm to room temperature and stirred under a nitrogen atmosphere for 2.5 hours at which time TLC (50% EtOAc/Petroleum Ether) revealed complete consumption of ester **13**. The mixture was cooled to 0°C and water (108 mL) was carefully added followed by 2 N HCl (54 mL). After evaporation of the THF *in vacuo*, the mixture was neutralised to pH 7 with 10 N NaOH and saturated with solid NaCl. The saturated aqueous solution was then extracted with EtOAc (5 X 100 mL), the combined organic layers washed with brine (200 mL), dried (MgSO₄), filtered and evaporated *in vacuo* to furnish the pure diol **14** as a clear colourless oil (16.97 g, 99%): $[\alpha]_D^{24} = -57.0^\circ$ (*c* = 0.61, CHCl₃); ¹H NMR (270 MHz, CDCl₃) δ 6.01-5.87 (m, 1H, NCO₂CH₂CH=CH₂), 5.36-5.20 (m, 2H, NCO₂CH₂CH=CH₂), 4.84 (br s, 1H, NCHCH₂OH), 4.60 (d, 2H, *J* = 5.31 Hz, NCO₂CH₂CH=CH₂), 4.39 (br s, 1H, NCHCH₂OH), 4.18-4.08 (m, 1H, 3.35, NCH₂CHOH), 3.90-3.35 (m, 4H, NCH₂CHOH, NCHCH₂OH, and OH), 3.04 (br s, 1H, OH), 2.11-2.03 (m, 1H, NCH₂CHOHCH₂), 1.78-1.69 (m, 1H, NCH₂CHOHCH₂); ¹³C NMR (67.8 MHz, CDCl₃) δ 157.1 (NC=O), 132.6 (NCO₂CH₂CH=CH₂), 117.7 (NCO₂CH₂CH=CH₂), 69.2 (NCH₂CHOH), 66.4 and 66.2 (NCO₂CH₂CH=CH₂ and NCHCH₂OH), 59.2 (NCHCH₂OH), 55.5 (NCH₂CHOH), 37.3 (NCH₂CHOHCH₂); MS (EI), *m/z* (relative intensity) 201 (M⁺, 2), 170 (M-CH₂OH, 100), 144 (M-OC₃H₇, 6), 126 (26), 108 (20), 68 (9); IR (Neat) 3394 (br, OH), 2946, 2870, 1679 (C=O), 1413, 1339, 1194, 1126, 1054, 980, 772 cm⁻¹; exact mass calcd for C₉H₁₃NO₄ *m/e* 201.1001, obsd *m/e* 201.1028.

Petroleum ether 40°-60° (100 mL) was added to a sample of NaH

(0.80 g of a 60% dispersion in oil, 20.12 mmol) and stirred at room temperature under a nitrogen atmosphere. After 0.5 hours the mixture was allowed to settle and the Petroleum Ether was transferred from the flask via a double-tipped needle under nitrogen. THF (100 mL) was added to the remaining residue and the mixture was cooled to 0°C (ice/acetone). The cool solution was treated dropwise with a solution of methyldiethylphosphonoacetate (3.69 mL, 4.23 g, 20.12 mmol) in THF (100 mL) under nitrogen. After 1 hour at room temperature, the mixture was cooled to 0°C and treated dropwise with a solution of the ketone **16** (3.0 g, 9.58 mmol) in THF (30 mL) under nitrogen. After 16 hours at room temperature, TLC (50% EtOAc/Petroleum Ether) revealed the complete consumption of ketone and further TLC (5% EtOAc/Petroleum Ether) revealed the formation of mainly the *exo*-product. The reaction mixture was cooled to 0°C (ice/acetone) and transferred via a double-tipped needle under nitrogen to another flask containing NaH (0.40 g of a 60% dispersion in oil, 10.1 mmol) at 0°C, freshly washed as above. The reaction mixture was maintained at 0 °C, and after 40 minutes TLC revealed the almost complete conversion to *endo*-product. The THF was evaporated *in vacuo* and the mixture partitioned between saturated NaHCO₃ (100 mL) and EtOAc (100 mL). The layers were separated and the aqueous layer extracted with EtOAc (2 X 50 mL). The combined organic layers were washed with brine (100 mL), dried (MgSO₄), filtered and concentrated *in vacuo* to give an orange oil. Petroleum Ether (100 mL) was added to a sample of NaH (1.41 g of a 60% dispersion in oil, 35.25 mmol) and stirred at room temperature under a nitrogen atmosphere. After 0.5 hours the mixture was allowed to settle and the Petroleum Ether was transferred from the flask via a double-tipped needle under nitrogen. THF (80 mL) was added to the remaining residue and the mixture was cooled to 0°C (ice/acetone). The cool solution

was treated dropwise with a solution of methyldiethylphosphonoacetate (6.47 mL, 7.41 g, 35.25 mmol) in THF (80 mL) under nitrogen. Method A: A solution of DMSO (0.25 mL, 0.27 g, 3.49 mmol) in CH_2Cl_2 (10 mL) was added dropwise over 35minutes to a solution of oxalyl chloride (0.87 mL of a 2.0 M solution in CH_2Cl_2 , 1.75 mmol) at -45°C (liq. N_2 /Chlorobenzene) under a nitrogen atmosphere. After stirring at -45°C for 40minutes, a solution of the alcohol **29** (0.51 g, 0.97 mmol) in CH_2Cl_2 (7 mL) was added dropwise over 35minutes at -45°C . After a further 45minutes, the reaction mixture was allowed to warm to room temperature and was diluted with CH_2Cl_2 (60 mL), washed with 1N HCl (60 mL), H_2O (60 mL), brine (30 mL), dried (MgSO_4), filtered and evaporated *in vacuo*. TLC (80% EtOAc/Petroleum Ether) of the crude material revealed complete reaction. Purification by flash chromatography (50% EtOAc/Petroleum Ether) furnished the protected carbinolamine **30** as a creamy glass (0.25 g, 49%).

Method B: A solution of the alcohol **29** (0.21 g, 0.40 mmol) in $\text{CH}_2\text{Cl}_2/\text{CH}_3\text{CN}$ (30 mL, 3:1) was treated with 4 Å powdered molecular sieves (0.15 g) and NMO (69 mg, 0.59 mmol). After 15minutes stirring at room temperature, TPAP (6.9 mg, 19.8 μmol) was added and stirring continued for a further 1 hour at which point TLC (80% EtOAc/Petroleum Ether) showed product formation along with some unoxidised starting material. The mixture was then treated with a further quantity of NMO (35 mg, 0.30 mmol) and TPAP (3.50 mg, 10 μmol), and allowed to stir for a further 1.5 hours after which time TLC revealed complete reaction. The mixture was evaporated *in vacuo* onto silica and subjected to flash chromatography (50%

A solution of the *bis*-alloc compound **78** (150 mg, 0.196 mmol) in CH₂Cl₂/CH₃CN (12 mL, 3:1) was treated with 4 Å powdered molecular sieves (0.2 g) and NMO (70 mg, 0.598 mmol). After 10 15 minutes stirring at room temperature, TPAP (7 mg, 19.9 μmol) was added and stirring continued for a further 2 hours at which time TLC (95% CHCl₃/MeOH) indicated formation, of the fully cyclised product along with the presumed semi-cyclised product **79**, and unreacted starting material **78** present in the reaction mixture. The mixture was then treated with a further quantity of NMO (35 mg, 0.299 mmol) and TPAP (3.5 mg, 9.96 μmol), and allowed to stir for a further 0.5 hours when TLC 20 revealed reaction completion. The solvent was evaporated *in vacuo* and the black residue was subjected to flash chromatography (98% CHCl₃/MeOH) to provide the pure protected carbinolamine **79** as a white solid (47 mg, 32%): ¹H NMR (270 MHz, CDCl₃) δ 7.23 (s, 2H_{arom}), 6.74 (s, 2H_{arom}), 5.90-5.65 (m, 2H, NCO₂CH₂CH=CH₂), 5.57 (d, 2H, *J* = 8.24 Hz, NCHCHOH), 5.26-5.07 (m, 8H, NCH₂C=CH₂ and NCO₂CH₂CH=CH₂), 4.67-4.10 (m, 14H, NCO₂CH₂CH=CH₂, NCH₂C=CH₂, OCH₂CH₂CH₂O and OH), 3.89 (s, 6H, OCH₃), 3.63 (m, 2H, NCHCHOH), 2.91 (dd, 2H, *J* = 8.79, 15.76 Hz, NCH₂C=CH₂CH₂), 2.68 (d, 2H, *J* = 16.10 Hz, NCH₂C=CH₂CH₂), 2.42-2.24 (m, 2H, OCH₂CH₂CH₂O); ¹³C NMR (67.8 MHz, CDCl₃) δ 166.7 (NC=O_{amide}), 150.1 (C_{quat}), 149.0 (C_{quat}), 141.7 (C_{quat}), 131.7 (NCO₂CH₂CH=CH₂), 130.6 (C_{quat}), 128.9 (C_{quat}), 128.8 (C_{quat}), 118.3 (NCO₂CH₂CH=CH₂), 114.7 (C-H_{arom}), 110.7 (C-H_{arom}), 109.8 (NCH₂C=CH₂), 85.9 (NCHCHOH), 66.9 (NCO₂CH₂CH=CH₂), 66.0 (OCH₂CH₂CH₂O), 59.7 (NCHCHOH), 56.1 (OCH₃), 50.7 (NCH₂C=CH₂), 35 35.0 (NCH₂C=CH₂CH₂), 29.7 and 29.1 (OCH₂CH₂CH₂O); MS (FAB)

A catalytic amount of tetrakis(triphenylphosphine)palladium (11 mg, 9.52 μmol) was added to a stirred solution of the *bis*-alloc-carbinolamine **79** (139 mg, 0.183 mmol), triphenylphosphine (4.8 mg, 18.3 μmol) and pyrrolidine (27 mg, 0.380 mmol) in $\text{CH}_2\text{Cl}_2/\text{CH}_3\text{CN}$ (13 mL, 10:3) at 0°C (ice/acetone) under a nitrogen atmosphere. A solution of potassium-*t*-butoxide in dry THF (0.5 M, 4.00 mL, 2.00 mmol) was added to as suspension of methyltriphenylphosphonium bromide (0.716 g, 2.00 mmol) in dry THF (2.00 mL). The resulting yellow ylide suspension was allowed to stir at 0°C for 2 hours before the addition of a solution of the bis-ketone **52** (0.50 g, 0.50 mmol) in THF (10 mL) at 10°C. The reaction mixture was allowed to warm to room temperature and stirring was continued for a further hour. The reaction mixture was partitioned between ethyl acetate (15 mL) and water (15 mL) and the organic layer was washed the sat. sodium chloride (20 mL) and dried over magnesium sulphate. Removal of excess solvent gave a brown oil that was subjected to flash column chromatography (50% ethyl acetate, 50% 40-60° petroleum ether) to afford the product as a yellow glass **206** (250 mg, 51%). $[\alpha]^{23.4}_D = -32^\circ$ (c 0.265, CHCl₃). ¹H NMR (CDCl₃): δ 0.00 (s, 12H), 0.88 (s, 18H), 2.37-2.40 (m, 2H), 2.69-2.75 (m, 4H), 3.80-4.62 (m, 20H), 4.61-4.63 (m, 4H), 4.98 (bs, 4H), 5.30-5.38 (m, 4H), 5.94-6.00 (m, 2H), 6.81 (s, 2H), 7.84 (s, 2H), 8.80 (bs, 2H).

An aliquot of hydrogen fluoride/pyridine complex (0.8 mL, 70% HF, 30 % pyridine) was added to a solution of the bis-silyl ether **206** (285 mg, 0.287 mmol) in THF (10 mL) at 0°C under a nitrogen atmosphere. Stirring was continued at 0°C for 30 minutes and the reaction mixture was then allowed to rise to room temperature over a 1 hour period. The reaction mixture was neutralised with sodium bicarbonate and extracted with dichloromethane (3 x 30 mL). The combined organic phase was washed with brine and dried over magnesium sulphate. Removal of excess solvent under reduced pressure afforded the product **78** as a yellow gum (218 mg).

1,1'-[[(Propane-1,3-diyl)dioxy]bis(11*S*,11*aS*)-10-(allyloxycarbonyl)-11-hydroxy-7-methoxy-2-methylidene-1,2,3,10,11,11*a*-hexahydro-5*H*-pyrrolo[2,1-*c*][1,4-benzodiazepin-5-one] (79)

A solution of dimethyl sulphoxide (0.55 mL, 7.75 mmol) in dry dichloromethane (10 mL) was added dropwise, over a 15 minute period, to a stirred solution of oxalyl chloride (0.32 mL, 3.67 mmol) in dichloromethane (10 mL) at - 45°C under a nitrogen atmosphere. The reaction mixture was allowed to stir for 35 minutes at - 45°C followed by addition of the diol **78** (1.01 g, 1.32 mmol) in dichloromethane (10 mL), at the same temperature, over 15 minutes. After a further 45 minutes a solution of triethylamine (1.50 mL, 10.76 mmol) in dichloromethane (10 mL) was added over a period of 15 minutes. The reaction mixture was allowed to stir at - 45°C for 30 minutes before being allowed to warm to room temperature over 45 minutes. The reaction mixture was diluted with water and the phases were allowed to separate. The organic phase was washed with 1M HCl (3 x 50 mL), sat. sodium chloride (50 mL) and dried over magnesium sulphate. Removal of excess solvent yielded the crude product, which was purified by flash column

A catalytic amount of tetrakis(triphenylphosphine)palladium (21 mg, 0.018 mmol) was added to a stirred solution of the bis-alloc-carbinolamine **79** (250 mg, 0.33 mmol), triphenylphosphine (10 mg, 0.033 mmol) and pyrrolidine (0.05 mL, 0.66 mmol) in dry CH₂Cl₂ (30 mL) at 0°C (ice/acetone) under a nitrogen atmosphere. The reaction mixture was allowed to stir for 2 hours before warming to room temperature over 1 hour.. The solvent was evaporated under reduced pressure and the resulting residue subjected to flash chromatography (98% CHCl₃/MeOH) to give the bis-imine target molecule **80** (SJG-136).

Preparation of Nitro Dimer Core

1',5'-Bis[2-methoxy-4-(methoxycarbonyl)phenoxy]pentane (208)

Neat diethyl azidodicarboxylate (19.02 mL, 21.04 g, 120.8 mmol) was added dropwise over 30 minutes to a stirred solution of methyl vanillate (**206**) (20 g, 109.8 mmol) and triphenylphosphine (43.2 g, 164.7 mmol) in anhydrous THF (400

mL) and the reaction mixture was allowed to stir at 0°C for 1 h. The cold reaction mixture was treated dropwise over 20 minutes with a solution of 1,5-pentanediol (**207**) (3.83 mL, 4.03 g, 53.0 mmol) in THF (4 mL). The reaction mixture was allowed to stir overnight at room temperature and the precipitated product (**208**) was collected by vacuum filtration. Dilution of the filtrate with methanol precipitated further product (**208**). The combined precipitate (12.3 g, 52 % based on pentanediol) was used in the next step without further purification: ¹H NMR (270 MHz, CDCl₃) δ 7.65 (dd, 2H, *J* = 2.01, 8.42 Hz), 7.54 (d, 2H, *J* = 2.01 Hz), 6.87 (d, 2H, *J* = 8.42 Hz), 4.10 (t, 4H, *J* = 6.59 Hz), 3.90 (s, 6H), 3.89 (s, 6H), 2.10-1.90 (m, 4H), 1.85-1.26 (m, 2H).

1',5'-Bis[2-methoxy-4-(methoxycarbonyl)-5-nitrophenoxy]pentane (209)

Solid copper (II) nitrate trihydrate (16.79 g, 69.5 mmol) was added slowly to a stirred solution of the bis-ester (**208**) (12 g, 27.8 mmol) in acetic anhydride (73 mL) at 0°C. The reaction mixture was allowed to stir for 1 hour at 0°C, the ice bath was removed and the reaction mixture was allowed to warm to room temperature a mild exotherm, c. 40°C, accompanied by the evolution of NO₂ occurred at this stage. After the exotherm had subsided stirring at room temperature was continued for 2 hours. The reaction mixture was poured into ice water and the aqueous suspension allowed to stir for 1 h. The resulting yellow precipitate was collected by vacuum filtration and dried in air to afford the desired bis nitro compound (**209**) (14.23 g, 98 %): ¹H NMR (400 MHz, CDCl₃ + DMSO) δ 7.45 (s, 2H), 7.09 (s, 2H), 4.14 (t, 4H, *J* = 6.31 Hz), 3.97 (s, 6H), 3.90 (s, 6H), 2.20-1.94 (m, 4H), 1.75-1.70 (m, 2H).

1',5'-Bis(4-carboxy-2-methoxy-5-nitrophenoxy) pentane (210)

A suspension of the ester **209** (9.0 g, 17.2 mmol) in aqueous sodium hydroxide (1 M, 180 mL) and THF (180 mL) was allowed to stir until a homogenous solution was obtained (2 days). THF

was evaporated under reduced pressure and the resulting aqueous suspension was filtered to remove any unreacted starting material. The filtrate was adjusted to pH 1, the precipitated product was collected by filtration and air dried to afford the desired bis-acid (**210**) (8.88 g). A higher than theoretical yield was obtained due to the inclusion of the sodium salt of acid. The salt may be removed by dissolving the bulk of the material in THF and removing the insoluble material by filtration: ¹H NMR (400 MHz, CDCl₃) δ 7.39 (s, 2H), 7.16 (s, 2H), 4.12 (t, 4H, *J* = 6.59 Hz), 3.95 (s, 6H), 2.00-1.85 (m, 4H), 1.75-1.67 (m, 2H).

Assembling the Bis Ketone Intermediate

1,1'-[[[(Pentane-1,5-diyl)dioxy]bis[2-nitro-5-methoxy-1,4-phenylene)carbonyl]]-bis[(2*S*,4*R*)-2-*t*-butyldimethylsilyloxymethyl-4-hydroxypyrrolidine] (211)

A catalytic amount of DMF (5 drops) was added to as stirred suspension of the acid **210** (5.39 g, 10.9 mmol) and oxalyl chloride (3.47 g, 2.38 mL, 27.3 mmol) in anhydrous THF (50 mL). Initial effervescence was observed followed by the formation of a homogenous solution, however after stirring overnight a suspension of the newly formed acid chloride was formed. Excess THF and oxalyl chloride was removed by rotary evaporation under reduced pressure and the acid chloride was resuspended in fresh THF (49 mL). The acid chloride solution was added dropwise to a solution of the (2*S*, 4*R*)-2-*t*-butyldimethylsilyloxymethyl-4-hydroxypyrrolidine (**2**) (6.3 g, 27.3 mmol), triethylamine (4.42 g, 6.09 mL, 43.7 mmol) and water (1.47 mL) in THF (33 mL) at 0°C under a nitrogen atmosphere. The reaction mixture was allowed to warm to room temperature and stirring was continued for 3 h. Excess THF was removed by rotary evaporation under reduced pressure and the resulting residue was partitioned between water (300 mL) and ethyl acetate (300 mL). The layers were allowed to separate and the aqueous layer was extracted with ethyl acetate (3 x 150 mL). The combined organic layers were then

washed with ammonium chloride (150 mL), sat. sodium bicarbonate (150 mL), brine (150 mL) and dried over magnesium sulphate. Filtration followed by rotary evaporation under reduced pressure afforded the crude product as a dark oil.

5 The crude product was subjected to flash column chromatography (3% methanol, 97% chloroform) and removal of excess eluent isolated (**211**) (3.70 g, 37% yield): ¹H NMR (270 MHz, CDCl₃) δ 7.65 (s, 2H), 6.77 (s, 2H), 4.52 (bs, 2H), 4.40 (bs, 2H), 4.17-4.10 (m, 6H), 3.92 (s, 6H), 3.77 (d, 2H, *J* = 10.26 Hz), 3.32 (td, 2H, *J* = 4.40, 11.35 Hz), 3.08 (d, 2H, *J* = 11.35 Hz), 2.37-2.27 (m, 2H), 2.10-2.00 (m, 6H), 1.75-1.60 (m, 2H), 0.91 (s, 18H), 0.10 (s, 12H).

1,1'-[[[(Pentane-1,5-diyl)dioxy]bis[2-amino-5-methoxy-1,4-phenylene)carbonyl]]-bis[(2*S*,4*R*)-2-*t*-butyldimethylsilyloxymethyl-4-hydroxypyrrolidine] (**212**)

15 A methanolic solution of hydrazine hydrate (1.25 mL, 1.29 g, 40.2 mmol of hydrazine, 20 mL of methanol) was added dropwise to a solution of the bis-nitro compound **211** (3.6 g, 3.91 mmol) in methanol (68 mL) gently refluxing over Raney nickel (510 mg of a thick slurry). After 5 minutes at reflux TLC (10% MeOH, 90% chloroform) revealed the incomplete consumption of starting material. The reaction mixture was treated with additional Raney nickel (c 510 mg) and hydrazine (1.25 mL) in methanol (20 mL) resulting in complete consumption of starting material. Excess Raney nickel was added to the reaction mixture to decompose unreacted hydrazine hydrate and the reaction mixture was then allowed to cool. The reaction mixture was filtered through celite to remove excess Raney nickel and the filter pad washed with additional methanol (Caution! Raney nickel is pyrophoric, do not allow filter pad to dry, use conc. HCl to destroy nickel). The combined filtrate was evaporated by rotary evaporation under reduced pressure and the residue re-dissolved in dichloromethane. The dichloromethane solution was dried over magnesium sulphate (to remove water associated with the hydrazine), filtered and evaporated to afford the product (**212**) as a foam (3.37 g,

91%): ^1H NMR (270 MHz, CDCl_3) δ 6.69 (s, 2H), 6.24 (s, 2H), 4.40-3.40 (m, 28H), 2.40-1.60 (m, 10H), 0.88 (s, 18H), 0.03 (s, 12H).

A solution of allyl chloroformate (0.806 mL, 0.916 g, 7.6 mmol) in dry dichloromethane (63 mL) was added, dropwise, to a solution of the bis-amine **212** (3.27 g, 3.8 mmol) and pyridine (1.26 g, 1.29 mL, 15.9 mmol) in dichloromethane (128 mL) at 10 0°C under a nitrogen atmosphere. The reaction mixture was allowed to warm to room temperature and to stir for 16 h. At which time TLC (10% MeOH, 90% Chloroform) revealed reaction to be complete. The reaction mixture was diluted with

15 dichloromethane (40 mL) and washed with sat. copper II sulphate (2 x 140 mL), water (120 mL) and sat. sodium chloride (120 mL). The organic phase was dried over magnesium sulphate, filtered and evaporated under reduced pressure to afford **213** as a foam (3.60 g, 92%): ^1H NMR (270 MHz, CDCl_3) δ 8.87 (bs, 2H), 7.66 (s, 2H), 6.77 (s, 2H), 6.05-5.80 (m, 2H), 5.40-5.15 (m, 4H), 4.70-4.50 (m, 6H), 4.38 (bs, 2H), 4.20-4.00 (m, 4H), 3.78 (s, 6H), 3.70-3.40 (m, 8H), 2.40-2.20 (m, 2H), 2.10-1.80 (m, 6H), 1.75-1.55 (m, 2H), 0.89 (s, 18H), 0.04 (s, 12H).

A solution of dimethyl sulphoxide (1.47 mL, 1.62 g, 20.7 mmol) in dry dichloromethane (32 mL) was added dropwise over 45 30 minutes to a stirred solution of oxalyl chloride (5.18 mL of a 2 M solution in dichloromethane, 10.35 mmol) at -60°C under a nitrogen atmosphere. After stirring at -50°C for 30 minutes, a solution of the bis-alcohol **213** (3.55 g, 3.45 mmol) in dichloromethane (53 mL) was added dropwise over a period of 50

minutes. The reaction mixture was allowed to stir at -60°C for 30 minutes prior to the dropwise addition of a solution of triethylamine (4.75 g, 6.54 mL, 46.9 mmol) in dichloromethane (27 mL). Triphenylphosphine, pyrrolidine and palladium tetrakis(triphenylphosphine) were added sequentially to a stirred solution of substrate in dry DCM. The reaction mixture was allowed to stir at room temperature under a nitrogen atmosphere for 2 h, at which time TLC (50% ethyl acetate and 50% 40-60° petroleum ether) revealed the complete consumption of starting material. Example 3 : Synthesis of Compounds of formula IIIOverview of Synthesis

The Biaryl PBDs **136**, **138** and **140** were obtained by removal of the Troc protecting group from the protected carbinolamines **135**, **137** and **139**. For compounds **136** and **138** the deprotection method of Dong et al, was employed (Cd/Pb, ammonium acetate buffer), however, this approach could not be applied to the preparation of **140** as this molecule contained a nitro group sensitive to the Cd/Pb couple. In this case a novel deprotection procedure involving the use of tetrabutyl ammonium fluoride was used. The protected biaryl carbinolamines were prepared by the Suzuki reaction, the common 7-iodo substituted protected carbinolamine **134** was exposed to the appropriate boronic acid in the presence of a palladium catalyst. This reaction is of wide scope as over 70 boronic acids are commercially available. The iodo substituted protected carbinolamine **134** was furnished by Swern oxidation of the primary alcohol **133**. The Swern procedure was particularly effective in this case but other oxidizing agents such as the Dess-Martin reagent, TPAP or pyridine sulphur trioxide complex and DMSO could also be employed. The primary alcohol **133** was afforded by coupling commercially available pyrrolidinemethanol to the Troc protected anthranilic acid chloride obtained by **132** by treatment with oxalyl chloride. The Troc protected acid was in turn prepared by exposing the anthranilic acid **131** to 2,2,2-trichloroethyl chloroformate. Other protecting groups can be used in place of Troc such as Nvoc, Teoc and Fmoc but care must be taken in choosing a protecting group as some groups such as Boc spontaneously form the isatoic anhydride when exposed to oxalyl chloride prior to the coupling step.

The 9-methoxy PBD (**101**) was prepared in an analogous fashion demonstrating the versatility of the approach.

The 8-amino PBD (**151**) was prepared by the removal of a Troc protecting group from the amino substituted protected carbinolamine **150**. The free amine was obtained by removal of an Fmoc protecting group under standard conditions

5 (piperidine/DMF) from the protected carbinolamine **149**. Swern oxidation of the primary alcohol **148** furnished **149** in good yield, the substrate for oxidation reaction was prepared by Fmoc protection of the aniline **147**. Reduction of the nitro compound **146**, with tin chloride furnished the aniline,
10 hydrogenation could not be employed to reduce the nitro group as the Troc system does not withstand these conditions. The nitro compound **146** was prepared by the coupling of the acid chloride derived from **145** with pyrrolidinemethanol in the presence of base. Finally, the protected anthranilic acid **145**
15 was furnished by exposing the commercially available 4 nitro anthranilic acid **144** to Troc Chloroformate.

The 8-benzyloxy-7,9-dimethoxy PBD (**143**, UP2022) was prepared by a slightly different approach which does not involve the use of anthranilic acid starting materials but proceeds
20 through 2-nitrobenzoic acid intermediates. The PBD was obtained from the protected carbinolamine **142** by removal of the Troc protecting group under the usual conditions. The protected carbinolamine was furnished by Swern oxidation of primary alcohol **141** which in turn was prepared by selective
25 protection of the amino alcohol **126** as the Troc carbamate by exposure to Troc Chloroformate in the presence of pyridine. The amino alcohol was obtained by reduction of the nitro compound **125** with Raney Nickel and hydrazine (again
hydrogenation could not be employed due to the presence of a
30 benzyl group). The nitro alcohol **125** was prepared by coupling pyrrolidine methanol to the requisite 2-nitrobenzoic acid **124**. This nitro benzoic acid was not commercially available and was prepared in four steps from the available syringic acid **87**. Nitration of the ester **122** was proceeded smoothly using Copper
35 nitrate in acetic anhydride. The ester **122** was obtained by standard methods.

The PBDs **96**, **113**, **120** and **194** were obtained in an identical fashion from the 2-nitrobenzoic acids **19**, **108**, **115** and **186**.

The dimer **90** was prepared in an analogous fashion from the core nitro compound **85**; the core was assembled by joining together two units of the phenol **84** via Mitsunobu etherification. The phenol **84** was derived from syringic acid **83** in a three step synthesis, the crucial step being the nitration of **82** which was performed with 70% nitric acid.

The phenolic PBD **130** was prepared by an analogous route to that used for the synthesis of the PBD **143**, however the requirement to incorporate a phenolic group prompted the use of a different protecting group, Teoc. The free PBD was obtained by treating the Teoc protected carbinolamine **129** with TBAF in warm acetonitrile. The phenol **129** was unmasked by the hydrogenolysis of the benzyloxy moiety of **128** in the presence of the Teoc protecting group (Troc would not survive under these conditions). The benzyloxy compound **128** was obtained by Swern oxidation of the primary alcohol **127** which was prepared by treating the amino alcohol **126** with Teoc chloroformate in the presence of base.

The organic layer was separated, washed with brine (150 mL), dried over MgSO₄, filtered and evaporated *in vacuo* to give a brown

solid. Purification by flash column chromatography (95% CHCl₃/MeOH) afforded the pure amine **202** as a greyish-pink solid (4.3 g, 82%). $[\alpha]_D^{20} = -78.6^\circ$ ($c = 1.02$, CHCl₃); $mp = 83-86^\circ C$; ¹H-NMR (CDCl₃, 270 MHz): δ 1.68-1.85 (m, 4H, H₄ + H₃), 2.00-2.04 (m, 2H, H₂'), 3.43-3.45 (m, 2H, H₃'), 3.49-3.58 (m, 2H, H₅), 3.67 (s, 3H, OCH₃), 3.72-3.78 (m, 2H, CH₂-OH), 4.04 (t, 2H, $J = 5.58$ Hz, H₁'), 4.22 (t, 1H, $J = 6.86$ Hz, Fmoc-CH), 4.41-4.44 (m, 3H, H₂ + Fmoc CH₂), 5.92 (br, 1H, NH), 6.23 (s, 1H, H₃_{arom}), 6.71 (s, 1H, H₆_{arom}), 7.27-7.41 (m, 4H, Fmoc_{aryl}), 7.62 (d, 2H, $J = 7.32$ Hz, Fmoc_{aryl}), 7.75 (d, 2H, $J = 7.33$ Hz, Fmoc_{aryl}); ¹³C-NMR (CDCl₃, 68.7 MHz): δ 24.9 (C₄), 28.6 (C₃), 29.1 (C₂'), 39.5 (C₃'), 47.3 (CH Fmoc), 51.0 (C₅), 56.6 (OCH₃), 60.4 (C₂), 61.1 (CH₂-OH), 66.4 (CH₂ Fmoc), 68.0 (C₁'), 102.0 (C₃_{arom}), 111.6 (C₆_{arom}), 120.0, 125.1, 127.0 and 127.7 (CH Fmoc_{aryl}), 128.0 (C_{arom}), 137.8 (C_{arom}), 141.3 (C Fmoc_{aryl}), 144.0 (C Fmoc_{aryl}), 148.2 (C_{arom}), 150.8 (C_{arom}), 156.6 (NC=O_{carbamate}), 171.9 (C=O_{amide}); MS (FAB) m/z (relative intensity): 546 ($M^+ + 1$, 11), 445 (10), 191 (14), 179 (100), 166 (51), 102 (70); HRMS (FAB) exact mass calcd for C₃₁H₃₇N₃O₆ ($M+H$): m/e 546.2526 obsd m/e 546.2532; IR (Nujol^b) ν : (cm⁻¹) 1698, 1622, 1588, 1506, 1476, 1404, 1228, 1173.

A solution of the amine **202** (1.1 g, 2.0 mmol) in DCM (40 mL) was cooled to 0°C (ice/acetone bath) and treated with pyridine (0.33 mL, 0.3 g, 4.1 mmol). A solution of trichloroethyl chloroformate (0.27 mL, 0.41 g, 1.9 mmol) in DCM (10 mL) was added dropwise over 30 minutes to the stirred mixture. The reaction mixture was allowed to warm to room temperature and stirred for a further 3 hours, at which time TLC (EtOAc) revealed complete loss of starting material. The reaction mixture was washed with 1 N HCl solution (50 mL), H₂O (2 x 50 mL), brine (50 mL), dried over MgSO₄, filtered and evaporated in vacuo. The crude residue was purified by flash column chromatography (98% CHCl₃/MeOH) to afford the pure

trichloroethyl-carbamate **203** as a brown solid (1.1 g, 74%).

All glassware, needles and cannulae used for this procedure had been previously dried overnight in an oven, and were assembled while still warm and the enclosed vessel flooded with nitrogen and evacuated three times. Freshly distilled DCM (6.6 mL) was transferred to the reaction vessel and the temperature lowered to -45°C (dry ice/ CH_3CN) under a nitrogen atmosphere. Oxalyl chloride (1.0 mL of a 2 M solution in DCM, 2.0 mmol) was transferred to the reaction vessel, followed by the dropwise addition over 30 minutes of anhydrous DMSO (0.3 mL, 0.3 g, 3.9 mmol) in dry DCM (4.2 mL). After stirring at -45°C for 30 minutes, a solution of the alcohol **203** (0.79 g, 1.1 mmol) dissolved in dry DCM (6.6 mL) was added dropwise over 50

minutes. The reaction mixture was allowed to stir at -45°C for 45 minutes, the mixture was then treated dropwise with DIPEA (1.9 mL, 1.4 g, 10.8 mmol) in dry DCM (4.2 mL) over 30 minutes at -45°C. After 35 minutes, TLC (97% CHCl₃/MeOH) revealed complete consumption of starting material. The reaction mixture was allowed to warm to room temperature, diluted with DCM (30 mL), washed with 1 N HCl solution (30 mL), H₂O (30 mL), brine (40 mL), dried over MgSO₄, filtered and evaporated *in vacuo*. Yellow lead (II) oxide (500 mg, 2.24 mmol) was dissolved in 50% aqueous acetic acid (5 mL) and the solution added slowly to a vigorously stirred suspension of cadmium dust (2.5 g, 22.4 mmol) in de-ionised H₂O (10 mL). The cadmium darkened as lead deposited on the surface and the clumps were broken up

carefully. After 20 minutes, the solid couple was filtered under vacuum, washed with H₂O and acetone and dried *in vacuo*. The lumps were crushed and stored in a closed vial.

The cadmium/lead couple (0.62 g, equiv. 0.56 g, 4.94 mmol Cd) was added in one portion to a solution of the Troc protected carbinolamine **204** (0.71 g, 0.99 mmol) and ammonium acetate (1.0 M, 9 mL) in THF (9 mL) at room temperature. The reaction mixture was stirred for 4 hours, during which time the reaction mixture became cloudy and opaque with a fluffy white precipitate. When reaction was complete as indicated by TLC (95% CHCl₃/MeOH), the solids were removed by filtration through Celite, and the THF removed by evaporation under reduced pressure. The filter cake was washed with several aliquots of EtOAc. The aqueous layer was extracted with EtOAc (3 x 15 mL), and the organic phase was dried over MgSO₄, filtered and evaporated *in vacuo*. Purification by flash column chromatography (97% CHCl₃/MeOH) furnished the target compound **205** as a brown solid (0.47 g, 90%) which was repeatedly evaporated *in vacuo* with CHCl₃ in order to obtain the N10-C11 imine form of the compound. $[\alpha]^{20}_D = +385.1^\circ$ ($c = 0.47$, CHCl₃); mp = 73-76°C; ¹H-NMR (CDCl₃, 270 MHz): δ 2.04-2.06 (m, 4H, H2 + H1), 2.27-2.29 (m, 2H, H2'), 3.45-3.47 (m, 2H, H3'), 3.67-3.73 (m, 2H, H3), 3.80 (s, 3H, OCH₃), 3.84-4.23 (m, 4H, H11a + H1' + Fmoc CH), 4.43-4.46 (m, 2H, Fmoc CH₂), 5.92 (br, 1H, NH), 6.82 (s, 1H, H6), 7.29-7.41 (m, 4H, Fmoc_{aryl}), 7.5 (s, 1H, H9), 7.61 (d, 2H, $J = 7.14$ Hz, Fmoc_{aryl}), 7.67 (d, 1H, $J = 4.40$ Hz, H11_{imine}), 7.75 (d, 2H, $J = 7.33$ Hz, Fmoc_{aryl}); ¹³C-NMR (CDCl₃, 68.7 MHz): δ 22.3 (C2), 29.3 (C1), 29.6 (C2'), 39.6 (C3'), 46.7 (C3), 47.4 (CH Fmoc), 53.7 (OCH₃), 56.0 (C11a), 66.3 (CH₂ Fmoc), 68.3 (C1'), 110.2 (C6), 111.4 (C9), 120.0 (C-H_{aryl} Fmoc), 120.5 (C_{arom}), 125.1, 127.0, and 127.7 (C-H_{aryl} Fmoc), 140.6 (C_{arom}), 141.3 (C_{aryl} Fmoc), 144.0 (C_{aryl} Fmoc), 147.7 (C_{arom}), 150.3 (C_{arom}), 156.6 (NC=O_{carbamate}), 162.5 (C11), 164.5 (C4_{amide}); MS (FAB) m/z (relative intensity): 526 ($M^+ + 1$, 15), 348 (7), 330 (4), 304 (4), 247 (12), 191 (15), 179 (100), 165 (17), 102 (40), 91 (10), 70 (13); HRMS (FAB) exact mass calcd for C₃₁H₃₂N₃O₅ (M+H): m/e 526.2264 obsd m/e

Examples 5 to 8 : Cytotoxicity Data

NCI In Vitro Cytotoxicity Studies

5 The National Cancer Institute (NCI), Bethesda, Maryland, USA has available an *in vitro* cytotoxicity screen which consists of approximately 60 human tumour cell lines against which compounds are tested at a minimum of five concentrations each differing 10-fold. A 48 hour continuous exposure protocol is used, where
10 cell viability or growth is estimated with an SRB protein assay.

Method

The test compounds were evaluated against approximately 60 human tumour cell lines. The NCI screening procedures were described in detail by Monks and co-workers (Monks, A *et al.*, Journal of
15 the National Cancer Institute, 1991, 83, 757). Briefly, cell suspensions were diluted according to the particular cell type and the expected target cell density (5000-40,000 cells per well based on cell growth characteristics), and added by pipette (100 μ L) into 96-well microtitre plates. The cells were allowed a
20 preincubation period of 24 hours at 37°C for stabilisation. Dilutions at twice the intended test concentration were added at time zero in 100 μ L aliquots to the wells. The test compounds were evaluated at five 10-fold dilutions (10^{-4} , 10^{-5} , 10^{-6} , 10^{-7} and 10^{-8} μ M). The test compounds were incubated for 48 hours in
25 5% CO₂ atmosphere and 100% humidity. The cells were then assayed using the sulphorhodamine B assay. A plate reader was used to read the optical densities and a microcomputer processed the readings into LC₅₀ values, which is the dosage required to kill half of the cells.

30 The results presented in examples 5 to 8 are LC₅₀ values which are below 10 μ M, which is taken to be the dividing line between cytotoxicity and non-cytotoxicity.

NCI Hollow Fibre Assay for Preliminary *In Vivo* Testing

The Biological testing Branch of the Developmental Therapeutics Program of the NCI has adopted a preliminary *in vivo* screening tool for assessing the potential anticancer activity of compounds identified by the large scale *in vitro* cell screen. For these assays, human tumour cells are cultivated in polyvinylidene (PVDF) hollow fibres, and a sample of each cell line is implanted into each of two physiologic compartments (intraperitoneal and subcutaneous) in mice. Each test mouse received a total of 6 fibres (3 intraperitoneally and 3 subcutaneously) representing 3 distinct cancer cell lines. These mice are treated with potential antitumour compounds at each of 2 test doses by the intraperitoneal route using a QD x 4 treatment schedule. Vehicle controls consist of 6 mice receiving the compound diluent only. The fibre cultures are collected on the day following the last day of treatment. To assess anticancer effects, the viable cell mass is determined for each of the cell lines using a formazyn dye (MTT) conversion assay. From this, the %T/C can be calculated using the average optical density of compound treated samples divided by the average optical density of the vehicle controls. In addition, the net increase in cell mass can be determined for each sample, as a sample of fibre cultures are assessed for viable cell mass on the day of implantation into mice. Thus, the cytostatic and cytotoxic capacities of the test compound can be assessed.

Generally, each compound is tested against a minimum of 12 human cancer cell lines. This represents a total of 4 experiments since each experiment contains 3 cell lines. The data are reported as %T/C for each of the 2 compound doses against each of the cell lines with separate values calculated for the intraperitoneal and subcutaneous samples.

Compounds are selected for further *in vivo* testing in standard subcutaneous xenograft models on the basis of several hollow fibre assay criteria. These include: (1) a %T/C of 50 or less

in 10 of the 48 possible test combinations (12 cell lines X 2 sites X 2 compound doses); (2) activity at a distance (intraperitoneal drug/subcutaneous culture) in a minimum of 4 of the 24 possible combinations; and/or (3) a net cell kill of 1 or more of the cell lines in either implant site. To simplify evaluation, a points system has been adopted which allows rapid evaluation of the activity of a given compound. For this, a value of 2 is assigned for each compound dose which results in a 50% or greater reduction in viable cell mass. The intraperitoneal and subcutaneous samples are scored separately so that criteria (1) and (2) can be evaluated. Compounds with a combined IP + SC score of 20, a SC score of 8 or a net cell kill of one or more cell lines are referred for xenograft testing. This comparison indicated that there was a very low probability of missing an active compound if the hollow fibre assay was used as the initial *in vivo* screening tool. In addition to these criteria, other factors (e.g. unique structure, mechanism of action) may result in referral of a compound for xenograft testing without the compound meeting these criteria.

20 **NCI Human Xenograft Studies**

These are carried out on nucle athymic mice with a disabled immune system. The human tumour tissue to be tested is implanted in their flanks, and whilst the control mouse receives no treatment, the others are subjected to varying doses of the test compound, which is administered intraperitoneally. The results are expressed as the toxicity of the compound, the amount of tumour growth, and the inhibition of growth.

Of the compounds tested, the above showed cytotoxicity against human lung, colon, CNS, melanoma, renal and breast cancer cell lines. Replacing the C-8 benzyloxy group in UP2003 (24) with a methoxy substituent (UP2065, 42) significantly changed the cytotoxicity profile, activity was lost against lung, CNS, and colon cancer cell lines (only reduced activity against Colo 205 remained). However, additional cytotoxic activity was gained against the melanoma cell lines SKMEL-2 and MALME-3M, the renal cell line RXF-393 and the breast cell line MDA-MB-435. Reduction of the ester moiety in UP2003 (24) to afford the alcohol UP2052 (33) resulted in increased activity in the lung cancer cell line NCI-460 and the colon cell line HCC-2998. Additional activity was registered against the lung cell line NCI-H522, the colon cell line HCT-116, the melanoma cell line M14 and the renal cancer cell line 786-0. Interestingly, the acetylated analogue UP2051 (31) exhibited attenuated or abolished activity in these cell lines (e.g. 7.6 μ M verses 0.5 μ M for UP2052 in the melanoma SK-MEL-2 cell line).

	MDA-N			9.0	6.6	0.6

Of the compounds tested, the above listed exert their cytotoxic effect (LC_{50}) most strongly in the Lung, Colon, CNS. Melanoma, Renal and Breast cell line panels. Within the group, it is apparent that exchanging a C-8 benzyloxy substituent (UP2004, 70) for a methoxy group (UP2064, 74) results in increased activity in the Melanoma panel. The methoxy analogue is more potent and acts against a greater number of cell lines. The methoxy analogue also exhibits improved activity against the colon cancer cell line Colo 205 and, in addition, the methoxy analogue exhibits activity against the renal cell line RXF-393 which is not observed with the benzyloxy compound. Replacing the electron rich dimethoxy A-ring with an iodo substituted

aromatic ring (UP2023, **64**) resulted in slight attenuation of activity in some cell lines, but the analogue showed activity against a wider spread of cell lines (i.e. 5 melanoma cell lines against only 3 for the benzyloxy analogue). Changing the nature of the C-ring ex-unsaturation from an alkene to a ketone (UP2067, **172**) lead to additional activity against the breast cancer cell line MDA-MB-435, renal cell line RXF-393, the melanomas MALME-3M, M14, SKMEL-28, the CNS cancers SF-539 and SNB-75 and against the lung cell line NCI-H522.

The PBD dimer UP2001 (**80**) exhibited potent and selective cytotoxicity activity against the lung cancer cell line NCI-H460, the colon cell line HCC-2998, the CNS cancer cell line SNB-75 and the melanoma cell lines MALME-3M (very potent, 0.08 μ M) and UACC-62 (very potent, 0.07 μ M), which may be attributable to its ability to cross link DNA.

UP2001 (**80**) and UP2004 (**70**) were subjected to the NCI Hollow Fibre assay described above. UP2001 has been selected for xenograft studies based on its combined IP + SC score (54) which was greatly in excess of 20, and its SC score which was higher than 8. UP2004 has been selected on the basis of its SC score, it being higher than 8.

Example 6(c) : Human Xenograft Studies on Compound 80 (UP 2001)

Human tumour xenograft studies on UP2001 were performed by the

Biological Testing Branch of the NCI as described above.

Athymic nude mice bearing MDA-MB-435 xenografts (human mammary tumour), Ovar-3 (human ovarian tumour), UACC-62 (human melanoma) or OVCAR-5 (human ovarian tumour) were treated at
5 doses of 0.67 (high), 0.45 (middle) and 0.3 (low) mg/kg/injection given once every 4th day for a total of 3 doses (6 mice per dose level with 20 controls).

UP2001 (80) was evaluated by measuring the toxicity of the drug and its ability to retard tumour growth.

10

Tumour	Toxicity			%T/C			%Growth Delay		
	High	Mid	Low	High	Mid	Low	High	Mid	Low
MDA-MB-435	3/6	1/6	2/6	toxic	3	3	41	41	41
OVCAR-3	0/6	0/6	0/6	7	20	46	73	73	9
UACC-62	0/6	0/6	0/6	22	28	67	43	43	43
OVCAR-5	0	0/6	0/6	52	45	38	16	28	32

15

Toxicity represents the number of mice which died as a result of treatment. %T/C represents the width of the tumours in the "test" mice (T) (as measured with calipers) compared to control untreated mice (C) and presented as a percentage. % Growth Delay represents the increase in the amount of time taken for
20 the tumors to reach an arbitrary size of 250 mg.

25

In the MDA-MB-435 xenografts UP2001 restricted tumour growth in treated mice to only 3% of the tumour growth observed in the control population. In addition, a 41% delay in the time taken to reach tumour mass of 250 mg was also observed. Some toxicity
towards the hosts was observed even at low dose.

30

A good dose response was observed for UP2001 (80) in the Ovar-3 xenografts. At the high dose, tumour growth in treated subjects was only 7% of that observed in the control population. At the medium dose the value was 20% and at the low dose the tumours in the treated mice were 46% of the size of the control tumours.

At the high dose a 73% growth delay in reaching a tumour mass of 250 mg was observed. No mice died as a result of exposure to UP2001 (80).

5 A similar dose response for tumour growth was observed in the UACC-62 xenografts for UP2001 (80). At the high dose treated tumours were 22% of the size of the control tumours. At the medium dose treated tumours were 28% of the size of the control tumours and at the low dose treated tumours were 67% of the size of the control tumours. Again no mice died as a result of exposure to UP2001 (80).

15 Results for the human ovarian tumour OVCAR-5 were less clear cut; approximately 50% tumour size reduction was observed and some growth delay was observed but activity appeared to be higher at lower concentrations. However, again, mice died as a result of exposure to UP2001 (80).

UP2001 (80) was also evaluated against the human CNS tumour SF-295. Athymic nude mice bearing SF-295 were treated at doses of 0.40, 0.27 and 0.18 mg/Kg by injection given intravenously once daily for a total of 5 doses.

20

Toxicity			%T/C			Tumour Free		
High	Med	Low	High	Med	Low	High	Med	Low
2/6	1/6	2/6	0%	0%	0%	4/4	5/5	3/4

UP2001 (80) displayed curative properties against SF-295 xenografts. At high and medium doses all the surviving mice were tumour free on day 27 of the experiment. At the lower dose 3 out of 4 mice were tumour free on day 27. Some toxicity was associated with the treatment, 2 mice dying at the high dose, 1 at the medium dose and two at the low dose. The higher intensities of the injection schedule may be reflected in the higher mortality observed.

Example 7 : In Vitro Cytotoxicity of compounds of Formula III

All of the compounds synthesised in example 3, were subjected to the NCI In Vitro Cytotoxicity screen. The results (LC_{50} ; μM) are set out below, and are illustrated in Figure 31.

The C-7-phenyl substituted compound UP2026 (136) showed cytotoxicity against cell lines in the human lung, colon, melanoma, renal and breast cancer panels. Interestingly, unlike other PBDs the molecule was inactive in the CNS cell line panel. However, UP2026 (136) was active against nearly all the members of the melanoma panel. Inclusion of a methoxy group in the C7 aryl moiety (138) resulted in increased selectivity as cytotoxicity was only observed in the lung cell line NCI-H522, the melanoma cell line SKMEL-2 and the renal cell line RXF-393. Introduction of a nitro group at C7 completely abolished cytotoxic activity, however, it seems likely that activity would be restored once the nitro group is reduced to an amine; in this way UP2029 (140) might prove to be a useful prodrug with

potential use in treating large hypoxic tumours. The C8 amino substituted PBD (UP2028, **151**) showed good activity in the lung, colon, CNS, melanoma, renal and breast cell line panels. On the other hand the trimethoxy PBD (UP2068, **96**) was only active in the lung, melanoma, renal and breast cell line panels.

Example 8 : In Vitro cytotoxicity of compounds of Formula IV:

The compounds synthesised in example 4, were subjected to the NCI In Vitro Cytotoxicity study. The results (LC_{50} ; μM) are set out below, and are illustrated in Figure 32.

Two of the four C8 PBD amides, UP2005 (**161**) and UP2008 (**167**), demonstrated cytotoxicity (LC_{50}) in the NCI assay. UP2005 (**161**) showed selectivity for the lung, CNS, melanoma and renal cancer in panels. The compound was particularly active in the melanoma panel exhibiting cytotoxicity against 5 out of the 8 melanoma cell lines. UP2008 (**167**) revealed a slightly different profile being active in the lung, colon, and melanoma panels. Again the molecule was particularly active in the melanoma panel.

Example 9: Further results for PBD dimer SJG-136 (UP2001, 80)

The compound synthesized in example 2(d) (SJG-136, 80) underwent some further assays.

5 The first assay, which is described in G.B.Jones, et al., *Anti-Cancer Drug Des.*, 1990, 5, 249, which is incorporated herein by reference, determines the effect of the test compound on the helix melting temperature of DNA. This assay is designed to give an indication of the strength and extent of cross-linking of the DNA strands by the test compound (i.e. a measure of the
10 stabilisation of the DNA upon ligand binding).

The melting temperature was determined for a 1:5 molar ratio of [ligand][DNA], where the calf thymus DNA concentration is 100 mM in aqueous sodium phosphate buffer (10 mM sodium phosphate + 1 mM EDTA, pH 7.00 \pm 0.01). For calf thymus DNA at pH 7.00 \pm
15 0.01, the melting temperature is 67.83 \pm 0.06°C (mean value from 30 separate determinations).

For a 1:5 molar ratio of [PBD]:[DNA], the PBD dimer 80 elevates the helix melting temperature (ΔT_m) of calf thymus DNA by an unprecedented 33.6°C after incubation for 18 hours at 37°C.
20 Under identical conditions, the C-ring-unsubstituted dimer DSB-120:

DSB-120

provides a ΔT_m of 15.1°C, demonstrating the extraordinary effect of introducing C2/C2'-unsaturation. In common with other PBD
25 dimers, 80 exerts most of its effect upon the GC-rich or high

temperature regions of the DNA melting curves. In a similar fashion to DSB-120, it provides some 60-80% of its stabilising effect without prior incubation, suggesting a kinetic effect in the PBD reactivity profile. However, the comparative ΔT_m curves show that, on a concentration basis alone, SJG-136 is ≥ 10 -fold more effective than DSB-120. Even at a [PBD]:[DNA] molar ratio of 1:100, SJG-136 still exhibits significantly better DNA binding affinity than the monomer tomamycin at a 1:5 [PBD]:[DNA] molar ratio.

Tomamycin

The results for a [PBD]:[DNA] ratio of 1:5 are summarised in the table below (All ΔT_m values ± 0.1 - 0.2°C)

Compound	Induced ΔT_m ($^\circ\text{C}$) after incubation at 37°C for		
	0 h	4 h	18 h
SJG-136 (80)	25.7	31.9	33.6
DSB-120	10.2	13.1	15.1
Tomamycin	0.97	2.38	2.56

The data presented in the above table show that SJG-136 (80) is the most potent DNA-stabilising agent known to date according to this particular assay.

The second assay determined the cytotoxicity of SJG-136 (80) in the human ovarian carcinoma cell line A2780 and its cisplatin-resistant subline A2780cisR, and compared this data with the cytotoxicity of the related dimer DSB-120 (see above) and Cisplatin. Relative to the parental line, the A2780cisR subline is known to have elevated GSH levels, an increased level of repair of DNA-cisplatin adducts, and a decreased ability to

uptake cisplatin (M.Smellie, et al., Br. J. Cancer, 1994, 70, 48).

The results, which were obtained by incubating the cells with the compounds for 96 hours at 37°C, and assessing the cell number using Sulforhodamine B, are presented in the table below:

	IC ₅₀ ^a (μM) for		
	A2780	A2780cis ^a	RF ^b
SJG-136 (80)	0.000023	0.000024	1.1
DSB-120	0.0072	0.21	29.2
Cisplatin	0.265	8.4	32

a Dose of compounds required to inhibit cell growth by 50% compared with control

b RF is the resistance factor (IC₅₀ resistant/parent)

The IC₅₀ value for **80** in the A2780 cell line is only 23 pM, representing a 320-fold increase in cytotoxicity compared to DSB-120 (IC₅₀ = 7.2 nM). More interestingly, whereas DSB-120 has a reduced potency in the cisplatin-resistant A2780cisR (IC₅₀ = 0.21 mM), SJG-136 is almost 9,000-fold more potent in this cell line with a similar IC₅₀ value (24 pM) to that in the normal A2780, giving a Resistance Factor of 1.1. The fact that both DSB-120 and cisplatin give Resistance Factors of 29.2 and 32, respectively, across this pair of cell lines suggests that SJG-136 may have potential in the treatment of cisplatin-refractory disease.

Example 10: Ovarian Carcinoma Cytotoxicity Assay

Compounds of the invention (and Anthramycin as a comparison) were evaluated for their cytotoxic activity in ovarian cell

lines by Dr Lloyd R. Kelland's group at The Institute of Cancer Research, Sutton, UK. The five cell lines investigated were SKOV-3, A2780/A2780cisR and CH1/CH1cisR (cisR denotes that the cell line is resistant to cisplatin).

Single viable cells were seeded in growth medium (160 μ L) in 96-well microtitre plates and allowed to attach overnight. The PBDs were then dissolved in DMSO (to give 20 mM drug concentrations) immediately prior to adding to the cells in quadruplicate wells. The final drug concentrations in the wells ranged from 100 μ M to 2.5 nM as follows: 100, 25, 10, 2.5, 1 μ M, 250, 100, 25, 10, 2.5 nM (drugs were diluted in growth medium and then 40 μ L added to the existing well volume of 160 μ L to give final concentrations as above). After 96 hours, the medium was removed and the remaining cells fixed by exposure to 10% trichloroacetic acid on ice for 30 minutes. The wells were then washed 3-4 times with tap water, air dried overnight and treated with 100 μ L of sulphorhodamine B (0.4%) dissolved in 1% acetic acid. Staining was allowed to continue for 10-15 minutes, then the wells were washed 3-4 times with 1% acetic acid, air dried and then added to Tris base (100 μ L of 10 mM). Plates were then shaken and absorbance readings at 540 nm were determined using a plate reader. By using the Quattro-Pro software package, the IC₅₀ values were calculated from plots of concentration versus percentage absorbance (compared with 8 untreated wells).

UP2095 (181)	<0.05	<0.05	<0.05	<0.05	<0.05

The most potent members of this group of compounds are those PBDs that possess aryl or vinyl substitution at the 2 position of the PBD: UP2089 (**177**), UP2092 (**179**) and UP2095 (**181**). Without wishing to be bound by theory, the potent activity of these molecules can probably be ascribed to the presence of conjugated *endo-exo* unsaturation in these molecules. *Endo-exo* unsaturation may improve the fit of the molecule in the minor groove of DNA, although the conjugated system may also indirectly affect the potency of the molecules through electronic and conformational effects. UP2089 (**177**) and UP2092 (**181**) are up to 100 times more potent than the natural product anthramycin, which also possesses conjugated *endo exo* unsaturation.

PBD dimers are able to cross-link DNA and block tumour cell replication and thus generally show high cytotoxicity. The PBD dimer UP2053, which possesses only *endo* unsaturation, exhibits potent activity in these ovarian cell lines. The dimer is markedly more cytotoxic than anthramycin but not as potent as the monomers UP2089 and 2092.

The remaining molecules of Formula I are monomers possessing only *endo* unsaturation, these molecules are broadly comparable with anthramycin. However, the ester UP2003 and the alcohol UP2053 are more potent than anthramycin against these ovarian tumour cell lines.

UP2100 (207)	<0.05	0.066	<0.05	<0.05	0.081

Compound UP2100 (**207**) has the structural formula:

213

207

and was synthesised by the same route as compound **70**.

UP2001 (**80**) exhibits cytotoxicity at picomolar/sub nanomolar levels across the ovarian tumour cell line panel. The potency of the molecule is probably due to its cross-linking properties coupled with the effect of exo saturation. UP2001 is markedly more potent than UP2053.

The monomers UP2004 (**70**) and UP2100 (**206**) exhibit good activity against the ovarian tumour cell lines comparable to that for anthramycin. UP2023 (**64**), which possesses a 7-iodo substituent is significantly less active than UP2004 (**70**), which contains two alkoxy groups at the 7 and 8 positions.

UP2086 (120)	0.84	0.45	1.6	2.2	2.5

UP2025 is the most potent monomer with two methoxy groups

donating electrons to the A-ring, however some compounds with 3 electron donating groups appear to be less cytotoxic (eg. UP2020-2022 and UP2066).

5 The simple phenyl substituted PBD (UP2026, **136**) shows micromolar activity in the ovarian tumour cell lines. Introducing an electron donating methoxy group into the phenyl substituent increases cytotoxicity (**138**) but the presence of an electron withdrawing nitro group reduces cytotoxic activity (**140**).
